DAY 3: KUBERNETES

Troubleshooting Minikube and Docker Issues

1. Cloning the Repository

Run the following command to clone the repository:

git clone https://github.com/PadmavathyNarayanan/kubernetes.git

2. Deleting and Purging Minikube

To reset Minikube, run:

minikube delete --all --purge

This deletes all profiles and removes the Minikube directory.

3. Restarting Docker

Stop and restart Docker using:

sudo systemctl stop docker sudo systemctl start docker

If there are permission issues, try killing Docker processes:

sudo pkill -f docker

4. Cleaning Up Docker Containers

Kill all running containers:

docker kill \$(docker ps -q)

Remove all stopped containers:

docker rm -f \$(docker ps -aq)

5. Pruning Unused Docker Data

To free up space, remove unused Docker objects:

sudo docker system prune -a --volumes -f

6. Checking for Processes Running on Port 8080

Check which process is using port 8080:

sudo netstat -tulnp | grep ":8080"

Kill the process by replacing <PID> with the actual process ID:

sudo kill -9 <PID>

If the process restarts immediately with a new PID, repeat the above step.

7. Final Steps

After resolving the issues, restart Minikube:

minikube start

Conclusion

By following these steps, you can effectively troubleshoot Minikube and Docker-related issues, ensuring a smooth development and deployment process. Always verify that Docker is running correctly and that no conflicting processes are occupying essential ports before starting Minikube.

Docker, Minikube, and Kubernetes Setup on Ubuntu

Prerequisites

- Ubuntu 24.04 (or any other supported version)
- Internet connection
- sudo privileges

Step 1: Update System Packages

sudo apt update

Step 2: Install Docker

sudo apt install docker.io -y

Verify installation:

docker --version

Enable and start Docker:

sudo systemetl start docker sudo systemetl enable docker

Step 3: Add User to Docker Group

To run Docker without sudo:

sudo usermod -aG docker \$USER newgrp docker

Verify Docker is running:

docker ps

Step 4: Install Minikube

Download and install Minikube:

curl -LO

https://storage.googleapis.com/minikube/releases/latest/minikube-linux-amd64

sudo install minikube-linux-amd64 /usr/local/bin/minikube

Verify installation:

minikube version

Step 5: Install Kubectl

curl -LO "https://dl.k8s.io/release/\$(curl -L -s https://dl.k8s.io/release/stable.txt)/bin/linux/amd64/kubectl" chmod +x kubectl sudo mv kubectl /usr/local/bin/

Verify installation:

kubectl version -client

Step 6: Start Minikube

minikube start

If the download fails, restart Docker:

sudo systemctl restart docker

Verify the Minikube node:

kubectl get nodes

Step 7: Check Running Containers

To list running Docker containers:

docker ps

Troubleshooting

1. Minikube Fails to Start

If Minikube fails due to missing images:

minikube delete --all --purge minikube start

2. Port Conflicts

If ports (e.g., 8080) are already in use:

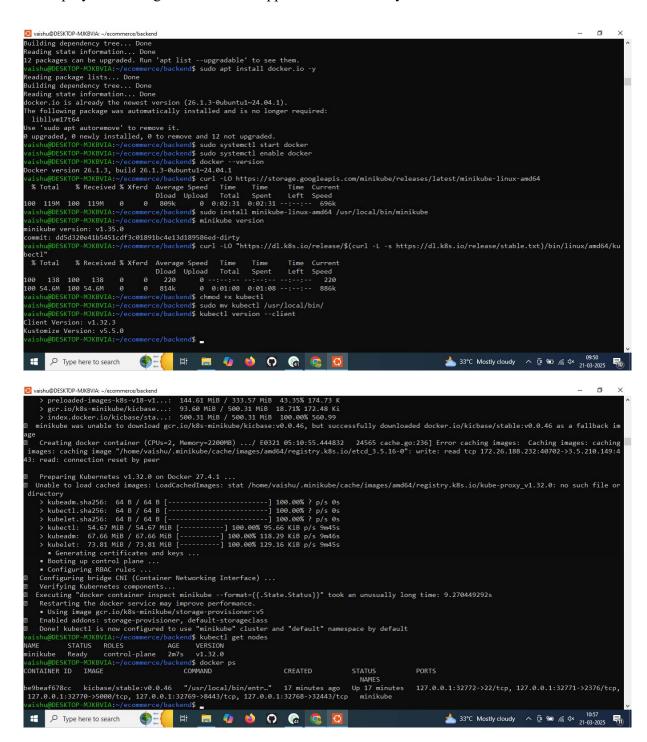

```
sudo netstat -tulnp | grep ":8080" sudo kill -9 <PID>
```

3. Restart Services

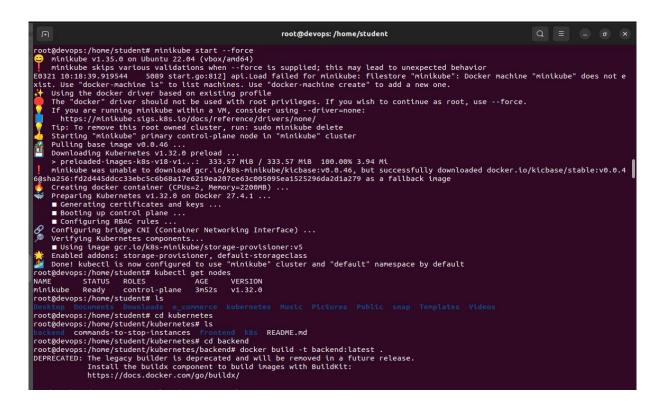

sudo systemctl restart docker minikube stop && minikube delete --all --purge minikube start

Conclusion

You have successfully set up Docker, Minikube, and Kubernetes on Ubuntu. Now you can deploy and manage containerized applications efficiently!

Kubernetes Backend Service Debugging

Commands Run

1. Start a Debug Pod

kubectl run debug --image=alpine --restart=Never -it -- sh

2. Check Backend Service Connectivity

curl http://backend-service:5000/products

3. List Running Pods

kubectl get pods

4. List Services

kubectl get services

5. Start a Test Pod for Debugging

kubectl run test-pod1 --image=alpine --restart=Never -it -- sh

6. Install Curl in Alpine Linux

apk add curl

7. Test API Response from Backend

curl http://backend-service:5000/products

Conclusion

The backend service was initially unreachable due to a DNS resolution issue. However, after verifying the pod and service configurations, it was confirmed that the backend service was correctly deployed and responding within the cluster. The issue may be related to the frontend's inability to resolve the backend service name correctly. Possible solutions include checking DNS settings, ensuring proper service discovery, and updating the frontend to use the correct internal service name or ClusterIP.
